

ADVANCED WEB EXERCISES== EVENING

Exercise1: Consider the tasks given in your notes on the last slide:
chapter 4 and chapter 5.

Exercise2: A school cafeteria in Kigali wants to develop a small JavaScript program to help calculate the total cost of meals purchased by a student. The cashier enters the price of a meal and the quantity purchased, and the system should automatically calculate the total amount to be paid. In addition, the cafeteria has introduced a discount policy: if the total amount is greater than 20,000 RWF, the student receives a 5% discount. Otherwise, no discount is applied.

Using JavaScript, develop a script that performs the following tasks:

1. Write a script that prompts the user to enter the price of a meal and the quantity purchased.
2. Calculate the total cost of the meals using JavaScript.
3. Use conditional statements to check whether the student qualifies for the 5% discount.
4. Display the final amount to be paid using `alert()`.

Exercise3: Try to design this table using react js.

Student Records

+ Add New Record

ID	NAMES	ADDRESS	PHONE	ACTIONS	
5	HKIZIMANA JAMES	KIGALI	0784593955	Edit	Delete
7	UWIMANA MARRY	MUHANGA	0789665613	Edit	Delete
8	KABERA PETER	KABEZA	0789665613	Edit	Delete

Exercise4: Try to design this login form using react js.

Exercise5: Rwanda Smart Banking: Loan Eligibility (PHP based)

The Rwanda Smart Banking system wants to automate loan eligibility checks. Develop a PHP script that captures a user's monthly income and employment status from a web form. The script must apply the following rules:

- A. If income $\geq$ 300,000 RWF and employment status is "Permanent," display: *Eligible for loan*.
- B. If income $\geq$ 300,000 RWF but employment status is "Contract," display: *Eligible with conditions*.
- C. If income $<$ 300,000 RWF, display: *Not eligible for loan*. The result should be printed directly to the browser page.

Exercise6: Rwanda Smart Transport: Fare Calculator (PHP based)

The Rwanda Smart Transport Authority is digitizing its bus fare system. You are tasked with developing a PHP script that captures a passenger's travel distance in kilometers from a web form. The script must compute the fare using the following rules:

- A. 0–5 km $\rightarrow$ 300 RWF
- B. 6–15 km $\rightarrow$ 500 RWF
- C. 16–30 km $\rightarrow$ 800 RWF
- D. More than 30 km $\rightarrow$ 1200 RWF

The program should display the entered distance, the calculated fare, and a short message confirming the fare amount. Results must be printed directly to the browser page.
